This inventory has not been subject to third-party verification.

Sample report: the company, its ledger and its figures are fictional.

§ 0 EDITOR'S NOTE ON THE FY 2025 INVENTORY

auditor brief

This report documents a footprint of 438.5 tCO₂e across the FY 2025 reporting period, covering 26.2% of the spend uploaded, decomposed and cited line by line in the pages that follow. Scope 1 (direct combustion) accounts for 52% of the total, driven principally by Natural Gas at 133.0 tCO₂e. Of 178 classified rows, 0% used activity-based factors (±5-10% accuracy) and the balance used spend-based factors (±25-40%, an engineering estimate for the method - §7.3.2 sanctions economic-value data and does not quantify its error); spend-weighted, 28% of the total came from high-confidence vendor or category matches. The pages that follow carry the full factor provenance, the transaction-level ledger and the methodology - the material an assurance engagement would start from, not a substitute for one.

§ 2 METHODOLOGY & STANDARDS

per GHG Protocol

This inventory is compiled under the GHG Protocol Corporate Accounting and Reporting Standard (Revised Edition) and the Corporate Value Chain (Scope 3) Standard. The hybrid methodology follows the §7.3.2 data hierarchy: Tier 2 activity-based factors where customer activity data was supplied; Tier 3 spend-based screening for the remainder.

Factor file version: **2.6.15-2026-10-05**. Spend-based factors carry an uncertainty band this report takes as $\pm 25\text{--}40\%$. That band is an engineering estimate for spend-based screening, not a figure published by the GHG Protocol: §7.3.2 sanctions the economic-value METHOD and does not quantify its error. Activity-based factors use EPA Emission Factors Hub Table C-1 for liquid fuels, EPA Stationary Combustion factors for natural gas and propane, SEAI 2025 provisional · 178.3 g CO₂/kWh, gross electricity supply (CO₂ only) grid intensity for electricity, and IPCC AR5 100-year GWP for refrigerant fugitive emissions. Activity factor file version: **1.8-be-eea2024-2026-09-30**. Activity-based accuracy: $\pm 5\text{--}10\%$.

For this report, **0** of **178** classified rows (**0%**) used activity factors; **178** used spend-based factors. Activity rows take precedence over spend rows for the same emission category - no double-counting.

Scope 1 captures direct emissions from owned or controlled sources; activity data supplants spend where supplied, else the spend-proxy method applies and is disclosed as such. Scope 2 captures purchased electricity. Scope 2 electricity is converted to kWh at the official price for the period and multiplied by SEAI 2025 provisional · 178.3 g CO₂/kWh, gross electricity supply (CO₂ only).

Cat 12 (End-of-Life). GHG Protocol Scope 3 Category 12 (end-of-life treatment of sold products) is **not applicable** to this report. The customer does not sell physical products, so there are no end-of-life emissions to attribute. A SaaS, service, or professional-services business legitimately reports Cat 12 as N/A under GHG Protocol Scope 3 Standard §5.12.

Scope 3 category coverage. Of the 15 GHG Protocol Scope 3 categories, this report renders results for **Cats 1, 2, 3, 4, 5, 6, 7, 12** - purchased goods and services (spend-based screening per §7.3.2), capital goods (equipment, IT and construction spend), fuel- and energy-related activities (Activity C - grid T&D losses derived from Scope 2), upstream transportation (when freight spend is present), waste generated in operations, business travel (when the relevant spend is present), employee commuting (see the limitation below), and end-of-life of sold products (Cat 12 where applicable; see §4b above for the three-branch disclosure). Each of these categories renders only when the classifier detects matching activity in the uploaded data - a report covering purely office-based SMB spend will typically render Cats 1, 3, and 12, while Cats 2, 4, 5, 6, 7 appear only when equipment, freight, waste, travel or commuting categories are populated. **Category 7 is bounded by the method**. A spend-based inventory can only see commuting the reporting entity PAID for - commuter benefits, transit passes and subsidies. Commuting borne by employees themselves does

not enter the ledger and therefore cannot enter this figure, and for most entities that is the larger share of it. A Category 7 total of zero here means no employer-paid commuting spend was found, not that employees do not commute. A complete Category 7 requires an employee survey of home-to-work distance and mode per the GHG Protocol Scope 3 Standard, which is outside a spend-based screening. Factor data is additionally provisioned for **Cats 8, 9** (upstream leased assets via EIA CBECS average-data intensity, downstream transportation via EPA Hub distance-based factors) - no route from customer input to these categories exists yet; rows exist in the factor file and are citable, but do not yet materialize in the report. Categories **10, 11, 13, 14, 15** (processing of sold products, use-phase of sold products, downstream leased assets, franchises, and investments) are not covered in this release and are disclosed as out-of-scope per GHG Protocol §5. A customer for whom any of these uncovered categories is material should supplement this screening with a category-specific inventory before using the numbers for regulatory filing or third-party assurance.

Energy is priced where and when it was bought. Each electricity, natural gas and road fuel purchase is converted to a quantity (litres, gallons, therms or kWh) at the official price for your country in the period of the transaction (European Commission Weekly Oil Bulletin, Eurostat nrg_pc_203 and Eurostat nrg_pc_205), net of any VAT or GST the business recovers. The quantity is then multiplied by the physical emission factor or the grid intensity. The quantity and price used are printed against each row of the transaction ledger.

Scope 3 uses factors for your country's economy. Purchased goods and services are converted with Open CEDA factors for Ireland: kg CO₂e per US dollar spent with each industry, from a multi-regional input-output model that includes the upstream emissions of the imports that industry uses. Each category takes the CEDA sectors of what was bought, priced at purchaser prices of the year of the spend. A good bought directly from abroad is still priced as output of your country's economy. The factor and the CEDA release and country used are printed against each ledger row.

Spend-based emission factors for Ireland purchases: CEDA by Watershed. Source: Open CEDA 2025 by Watershed, accessed on 2026-09-29 from <https://registry.opendata.aws/open-ceda>, licensed under CC BY-SA 4.0 (<https://creativecommons.org/licenses/by-sa/4.0/>). Changes by aisustainablefuture.com: CEDA sectors averaged to our spend categories, with stores and wholesalers mapped to the goods they sell; converted from 2023 US dollars at producer prices to purchaser prices of the year of the spend (CEDA's latest index year for later spend), using CEDA's sector price index and, for sectors CEDA gives a trade margin (its purchaser-producer ratio), trade and transport margins priced at CEDA factors for the same country; spend converted to US dollars at the ECB reference rate for the month of each purchase (a fixed rate for a currency the ECB does not publish); a country value that is zero, or more than three times or less than a third of that country's usual level against its region, replaced by CEDA's regional average scaled to that level. The adapted factors in this report are licensed under CC BY-SA 4.0. Source data provided as is, without warranties. No endorsement by Watershed is implied.

Part of Scope 1 (propane, 4% of it) is still anchored to US fuel prices. The spend-based Scope 1 factors in this pack are kg CO₂e per dollar, derived as a published physical factor divided by a US retail price - \$3.50 a gallon for motor gasoline, \$4.00 for diesel, \$1.00 a therm for natural gas. Applying them to spend in a country with different fuel prices implies a quantity of fuel that is wrong by the ratio of the two prices, and the error runs the same way for every affected row. Where local fuel is dearer than in the US - which is most of Europe - this OVERSTATES your Scope 1, materially and outside the uncertainty band quoted above. The fix is exact and takes one number off your fuel invoice: enter litres, gallons, kWh or therms of fuel purchased rather than what you paid. The physical factors are combustion chemistry and do not vary by country, so a quantity gives a correct answer everywhere. Until then, treat that part of Scope 1 as an upper bound; the rest is priced at your country's official prices for the period.

Boundary, base year and recalculation. Organizational boundary: **Operational control**. Base year: **2025**. Where either is unstated the customer did not supply it, and this report makes no assumption on their behalf; both are required for a conforming inventory and both are collected at upload. Recalculation policy: the base year is restated when a structural change (acquisition, divestment, outsourcing), a methodology change, or a discovered error alters base-year Scope 1 + 2 by more than 5%. That threshold is this report's declared significance threshold per GHG Protocol Chapter 5; a screening inventory has no prior period to restate, so the policy governs from this year forward.

Gross figures, biogenic carbon and per-gas reporting. Every total in this report is GROSS: no purchased offsets, renewable energy certificates or allowances have been deducted, and the engine has no field in which to enter them. Biogenic CO₂ is not separately quantified - a spend-based screening cannot distinguish the biogenic fraction of a fuel or material purchase from its fossil fraction, so no biogenic figure is claimed either way. Per-gas: Scope 1 combustion is reported as CO₂ and non-CO₂ (CH₄ and N₂O combined) because the EPA Hub publishes the combustion factor as CO₂ with a single non-CO₂ uplift; splitting CH₄ from N₂O would require per-gas factors this engine does not carry, and inventing the split would be worse than declining it. Spend-based rows are blended CO₂e by construction and cannot be decomposed at all. No PFC or SF₆ sources were identified.

Amounts were in EUR. Non-USD amounts were converted to USD using static FX rates (vintage: **February 2026**) before emission factors were applied. Conversion details appear in the Transaction Ledger.

Calculation. For spend-based rows: $\text{tCO}_2\text{e} = (\text{spend USD}) \times (\text{factor kg/USD}) \div 1,000$.
 For activity-based rows: $\text{tCO}_2\text{e} = (\text{physical quantity}) \times (\text{per-unit factor}) \div 1,000$.
 Refrigerant fugitive emissions: $\text{tCO}_2\text{e} = (\text{refrigerant kg}) \times (\text{GWP}_{100}) \div 1,000$.

Rows were classified on the deterministic keyword path (vendor names, account names and descriptions mapped to EEIO commodity codes); Claude was not used for this upload. Vendor name

takes precedence over expense_category when both are present. This report was generated on **05 October 2026**.

Sensitivity. The range below is asymmetric because the two error sources are. Factor uncertainty for spend-based screening is taken as $\pm 25\text{--}40\%$ and cuts both ways; incomplete coverage only ever understates. Applied to the inventory total (**438.5** tCO₂e), the range is **263.1–613.9** tCO₂e. **What this range does NOT cover:** misclassification. A row assigned to the wrong category moves by the **RATIO** of two factors, not by a percentage, and the factors in this pack span roughly two orders of magnitude – so a single misrouted row can exceed the whole band. The per-row factor and mapping logic in the transaction ledger are there to make that checkable. Substituting activity data for spend in high-impact categories tightens the factor half toward $\pm 5\text{--}10\%$.

This draft is intended for screening, supplier-disclosure response (CDP, Walmart Project Gigaton, Microsoft Supplier Sustainability), and management decision support. For formal regulatory filings or third-party assurance, supplement with primary activity data across material categories and engage an ISO 14064-3 reviewer.

§ 2.1 SCOPE BOUNDARY STATEMENT

This inventory declares **Scope 1** (direct fuel combustion), **Scope 2** (purchased electricity), and **Scope 3** (value chain) emissions. Scope 3 categories assessed from your spend data: Category 1 - Purchased Goods and Services; Category 2 - Capital Goods; Category 3 - Fuel- and Energy-Related Activities (not included in Scope 1 or Scope 2); Category 4 - Upstream Transportation; Category 5 - Waste Generated in Operations; Category 6 - Business Travel. Other value-chain categories are included only where they can be identified from spend; those not derivable from the ledger (for example employee commuting or use of sold products) are not assessed. Of **238** line items, **178** were classified into Scope 1, 2 or 3; **60** were excluded as non-emission (payroll, tax, rent and similar). Of the spend uploaded, **26.2%** carries an emission factor, **73.9%** is non-emitting and was deliberately excluded (payroll, tax, rent and similar), and **0.0%** could not be identified. Only the last of those three understates your footprint.

§ 2.2 DATA INTAKE DECISIONS · STRUCTURAL

auto-detected

Before parsing the upload, the engine inspected its structure and auto-detected the settings below. Each decision normalizes the data to a consistent internal format before emission factors are applied, preserving the ability to reconcile each line against your general ledger.

File encoding	UTF-8
Decimal convention	US (1,234.56)
Negative amount format	Hyphen (-1234.56)
Date convention	DD/MM/YYYY (day-first)
Localized column headers mapped	Date→date, Contact→vendor, Account Name→category

Additional notes. Mapped localized column headers: 'Date'→date, 'Contact'→vendor, 'Account Name'→category;
Detected date format: DD/MM/YYYY (based on 238 date cells with majority-vote convention)

§ 3 DATA QUALITY · CONFIDENCE & PROVENANCE

rows classified

28% of total emissions came from rows classified at high confidence (vendor or category matched at ≥ 0.8). The balance sits in medium- or low-confidence rows - review those in the Transaction Ledger if citing specific line items. Top 3 vendors represent 100% of Scope 1 spend (3 distinct vendors total) - reduction effort concentrated on those three accounts has the highest leverage. **Note.** 42 of the 178 rows that carry a factor (24%) were matched on weaker evidence than a direct vendor hit (< 0.8). Common causes: partial vendor names, ambiguous expense categories, or contradictory vendor/category pairs. Cleaner vendor names or activity-data overrides would tighten these rows. Rows that could not be matched at all are a separate figure and are reported in § 2.1 as uncovered spend.

Classification method	GHG Protocol spend-based (automated)
Emission-factor source	Scope 1 and 2: SEAI 2025, priced at European Commission Weekly Oil Bulletin, Eurostat nrg_pc_203 and Eurostat nrg_pc_205; US EPA factors at US prices for propane, which has no price series here; Scope 3: CEDA by Watershed (Open CEDA 2025, CC BY-SA 4.0, adapted); factor pack v2.6.15-2026-10-05
Rows uploaded	238
Rows priced into the totals	178
High-confidence mappings	136
Items for review	42
Total transactions flagged	0

Industry-standard estimation per GHG Protocol Corporate Standard (2015 Revised). Spend items were classified via automated mapping with keyword and vendor recognition. For tighter accuracy, supply actual activity data (kWh, litres, km) where available.
